Problem Overview

Applications: safety-critical systems

Definition

22/10/2020

4/20

Safety-critical systems are those systems whose failure could result in loss of life, significant property damage, or damage to the environment. (Knight et al. 2002)

Safety Critical Systems using RL

- Cooling systems (Li et al. 2018)
- Autonomous-driving vehicles (survey by Kiran et al. 2020)
- Industry robots Sarcos' Humanoïd DB used RL to learn a pole-balancing task (Schaal, 1996).

Today Sarcos' Guardian suits are rented \$ 150.000 a vear

Alex Vigneron CCE for safe I

Imagine...

A brave robot having to look for a marvelous treasure kept in a solid chest inside volcanic caves filles with lava pits...

It needs to get the treasure while avoiding lava. Where should it tread?

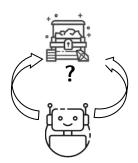

- Get treasure = objective
- Avoid lava = constraint
- Where to tread = policy

Alex Vigneron

Reinforcement Learning Paradigm 🛦

Policy π

A probability distribution parameterised by a vector θ over actions given states. $\pi_{\theta}(s_i) \mapsto \{(a_{i0}, p_{i0})...(a_{in}, p_{in})\}$

Concept

Agent interacts with environment looking for optimal behaviour, receives rewards, modifies its actions to maximise reward

- Input : MDP
- Output : Policy $\Pi = max(\sum_{s \in \mathcal{P}} \mathcal{R}(s, a))$

Markov Decision Process (Sutton & Barto 2017)

MDP characterised as a tuple (S, A, P, R)

- lacksquare \mathcal{S} , set of states $\mathcal{S} = \{s_0, s_1...s_n\}$
- A, set of actions $A = \{a_0, a_1...a_n\}$
- lacksquare \mathcal{R} , reward function $\mathcal{R}(s,a)\mapsto \mathbb{R}$
- \mathcal{P} , transition probability function $\mathcal{P}(s,a) \mapsto \mathbb{R}^+$ where for a fixed s, $\sum_{s} \mathcal{P}(s,a) = 1$
- Initial distribution state

6/20

Constraints in traditional RL: an example de

Problem

Avoiding lava while obtaining the treasure

Solution

Lava is encoded as a (major) negative reward

Effect

First iterations: agent explores any state

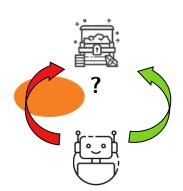

(including lava states)

Following iterations: agent learns it should

not tread lava

Problem

Lava is still an option... \longrightarrow no guarantee on lava constraint

Constrained Cross-Entropy

Source: Medium/Udacity Serrano

Entropy (Shannon's)

Entropy is a measure of our lack of information about the microstate of a system (Machta et al. 1999)).

Cross-Entropy

Cross-entropy is commonly used to quantify the difference between two probability distribution.

Constrained Cross-Entropy

This functions incorporates the constraints on the system in a generic fashion, irrespective of the form or even the number of the constraints (Niven et al.,

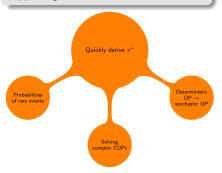

8/20

CE: an intuition

Idea

9/20

Probabilistic approach to maximise possibility of an unlikely event happening.

Algorithm

- Sample from a distribution of policies
- Select a set of elite samples and use them to update policy disribution.

Example

Unlikely event = having a policy which both maximises rewards and respects all constraints.

22/10/2020 Alex Vigneron CCE for sa

CCE Algorithm

```
Input: G, H, upper bound b, set of parameterised policies \Pi_{\theta},
          NEF family F
  Output: П*
1 Initialise (random, feasible, unfeasible)
   while stopping rule is not satisfied do
      Sample over parameters \theta of policy
2
       for each policy \pi \in \Pi with \theta parameters do
           Simulate \pi_{\theta}
3
            Compute and store G(\pi_{\theta}) and H(\pi_{\theta})
      end
4
      Sort \theta in ascending order of H-value
       Let \psi be the first k elements
       if H_{\theta yb} < b then
           Sort \theta_{\pi} with H_{\pi\theta}b in descending order of G
6
      end
7
      Estimate through CE
       Ensure new p.d.f. still ∈ intitial NEF family
       Update
```

10/20

9 end

L-function

The L function

Optimised through learning!

$$L(\mathbf{v}, \rho) = \begin{cases} if \xi_{H}(\rho, \mathbf{v}) > d \longrightarrow \mathbb{E}_{\theta \sim f_{\mathbf{v}}} [\mathcal{G}(\pi_{\theta}) \ \delta(\mathcal{H}(\pi_{\theta}) \leq \xi_{H}(\rho, \mathbf{v}))] \\ else \longrightarrow \mathbb{E}_{\theta \sim f_{\mathbf{v}}} [\mathcal{U}(\pi_{\theta}) \ \delta(\mathcal{U}(\pi_{\theta}) \geq \xi_{U}(1 - \rho, \mathbf{v}))] \end{cases}$$
(1)

- v, parameter for probability distribution
- \bullet $f_{\mathbf{v}}(\theta)$, probability distribution over parameter θ
- d: acceptability threshold
- ullet $\mathcal{G}(\pi_{\theta})$, expected gain with regards to policy π with parameters θ
- \blacksquare $\mathcal{H}(\pi_{\theta})$ expected cost of constraints with regards to π with parameters θ
- $\xi_F(\rho_i, \mathbf{v})$, p-quantile of the p.d.f. parameterised by \mathbf{v}
- \bullet $\delta(F)$... maps result to a boolean
- ullet $\mathcal{U}(\pi_{\theta})$: expected reward $\mathcal{G}(\pi_{\theta})$ if respects constraints, 0 otherwise

CCE recap

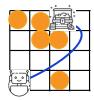

The problem at hand

Task: robot navigation with only local sensors

- $\mathbf{S}, \mathcal{A}, \Pi$ sets of states, actions and policies
- Objective function $\mathcal{O}: (\mathcal{S} \times \mathcal{A})^n \longrightarrow \mathbb{R}^+$
- Cost function $C: (S \times A)^n \longrightarrow \mathbb{R}$
- Deterministic Transition function
- $\mathcal{G}: \Pi \longrightarrow \mathbb{R}^+$ expected value of rewards over Π
- $\mathcal{H}: \Pi \longrightarrow \mathbb{R}$ expected value of constraints over Π

Trust Region Policy Optimisation i

Trust region

Source: MC.Al

TRPO (Schulman et al. 2015)

- Unconstrained RI
- Used as a safeguard against policy gradient disasters (especially in high-curvature functions).
- Restricts policy moves so changes are not too agressive.
- Allows one policy update per iteration.

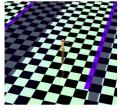

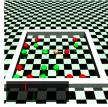

Constrained Policy Optimisation &

CPO (Achiam et al. 2017)

- Constrained RL
- Defines a risk function to ensure agent's security
- Both reward and risk are taken into account at each step
- Promotes safe exploration

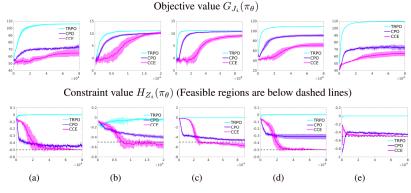

(a) Humanoid-Circle

(b) Point-Gather

Source: Achiam (2017)

Baseline

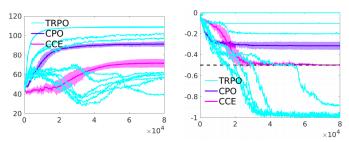

x-axis: number of sample trajectories

y-axis: expectation of cumulated reward/punishment for CPO/TRPO and learned policy distribution for CCE

Alex Vigneron

Baseline i

TRPO's unconstrained approach is insufficient, merely optimising objectives is not enough to output feasible policy.

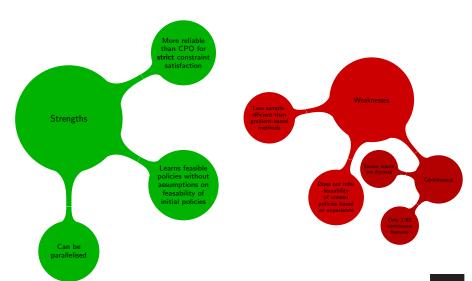

17/20

CPO needs more samples to find a feasible policy or converges to infeasible policy (especially if constraint is non-Markovian).

Alex Vigneron

CCE for safe RL

Limitations of the paper i

Perspective

22/10/2020

19/20

Postulate that it is very hard to encode constraints as reward functions, but though hard, this is feasible (Geibel *et al.* 2005, Abe *et al.* 2010, Tong *et al.* 2000)

Experimental setting

Both goal and danger region are compact. This simplification does not take into account the difficulty of proper exploration in sparse settings.

Thank you for your time

In a nutshell

- CCE uses a probabilistic approach to solve safe RL problems.
- CCE can work while initialised with unfeasible policy, which is often not the case in safe RL.
- The key function is $\mathcal{L}(\mathbf{v}, \rho)$ since it takes into account both \mathcal{G} the objective function and \mathcal{H} the constraint function.

Constrained Cross-Entropy

Entropy (Shannon's)

Skewed Probability Distribution (unsurprising) : Low entropy. Balanced Probability Distribution (surprising) : High entropy.

$$\mathcal{H}(X) = -\sum_{i=1}^{n} P(x_i) log(P(x_i))$$

 $X = (x_1, ..., x_n)(2)$

Cross-Entropy

$$\mathcal{H}(p,q) = -\mathbb{E}_{p}[log(q)] = \mathcal{H}(p) + \mathcal{D}_{KL}(p||q)$$
(3)

Constrained Cross-Entropy

This functions incorporates the constraints on the system in a generic fashion, irrespective of the form or even the number of the constraints (Niven et al., 2003).
